TIME ATTRACTION LAW - Experimental Test Proposal

Author: David Szabolcsi, Independent Researcher, Zurich | DOI: 10.5281/zenodo.23234825 (new) / 10.5281/zenodo.22983682 (original) | Contact: Unbekanntedavid@gmail.com

1. Hypothesis

Time flow factor f_L = exp(-gamma_L * rho_bar_L), where gamma_L = G_N * L^2 / c^2. Hypothesis: time is attracted to mass density - denser matter slows time beyond GR prediction.

2. Testable Prediction

With 10-ton Pb block (rho = 11.34 g/cm3) at L=0.5 m from Sr optical clock vs far position 3.0 m, predicted differential fractional frequency shift Delta f / f ~ 5 x 10^-19. Requires 72h lock-in measurement with block on/off on linear rail. Background: Sr clock stability 1.2 x 10^-18.

3. Experimental Setup

Sr Clock #1 (reference, far) | Sr Clock #2 (probe) + 10t Pb on rail [NEAR 0.5m / FAR 3m] | Differential measurement Delta f = f_near - f_far. Pb block moved automatically, lock-in analysis.

4. Why Sr clocks

Signal is 0.4 x clock noise - needs averaging but within reach of PTB, NIST, JILA, ETH class systems. No new hardware needed, only rail + Pb.

5. Falsifiability

If Delta f/f < 1 x 10^-19 after 72h averaging, law is falsified at this scale. If ~5e-19 and scaling with rho_L as exp(-gamma*rho), law is supported. Clear pass/fail criterion.

6. What we ask

72h parasitic time on existing Sr setup. We provide Pb logistics concept and data analysis (fit to f_L = exp(-gamma_L * rho)). Co-authorship offered. All data open via Zenodo CC BY-NC 4.0. Motto: 'Time does not just pass, it is attracted.'
